ABSTRACT: Immunohistochemical detection of serotonin (5-HT) and tubulin in *D. gyrociliatus* and *D. taeniatus* revealed similar anatomical structures of ventral locomotory ciliary field and underlying 5-HT-immunoreactive nerve network in both young juvenile and adult worms. External application of 5-HT and serotonin biochemical precursor (5-HTP) resulted in increased level of 5-HT within nervous structures in both juveniles and adults. However, while 5-HT and 5-HTP increased speed of gliding locomotion in juvenile worms, the same concentration of drugs decreased significantly or did not affect locomotion of adults. Thus, 5-HT activates the gliding locomotion in juvenile Archiannelid worms similar to larvae of annelids, molluscs and flatworms which use cilia for locomotion. Altered mode of 5-HT action on the locomotion of adult Archiannelid worms indicates reorganization of the 5-HT cilia controlling system during Dinophilid maturation.

РЕЗЮМЕ: Иммунохимическое маркирование серотонина (5-HT) и тубулина у *D. gyrociliatus* и *D. taeniatus* выявило сходные анатомические структуры у ювенильных и взрослых особей: центральную локомоторную ресничную полоску и подлежащую 5-HT-имmunoreактивную нервную сеть. Аппликация 5-HT и его биохимического предшественника (5-HTP) приводила к повышению уровня 5-HT в нервных структурах ювенильных и взрослых особей. Однако, в то время как скорость ресничной локомоции в ответ на аппликацию 5-HT и 5-HTP у ювенильных червей увеличива-

лась, те же концентрации веществ значимо снижали или не оказывали эффекта на взрослых особей. Таким образом, 5-HT активирует локомоцию ювенильных архианнелид, таким же образом, как и локомоцию личинок аннелид, моллюсков, и взрослых плоских червей, которые используют реснички для локомоции. Противоположный (замедляющий) эффект действия 5-HT на локомоцию взрослых архианнелид может указывать на реорганизацию сигнальной 5-HT системы, задействованной в контроле биения ресничек при продвижении динофилид по жизненному циклу.

Introduction

Dinophilid worms belong to the Archianne-lida group and are represented by two species: *Dinophilus gyrociliatus* (Schmidt, 1857) and *Dinophilus taeniatus* (Harmer, 1889). Normally, dinophilid worms exhibit two modes of locomotion: gliding using the ventral field cilia and swimming using circulary ciliary bands. As in many other annelid and molluscs, serotonin containing nerve elements accompany the locomotory ciliary elements (Christopher et al., 1996; Pavlova, 2001). Thus we suggested that serotonin (5-HT) should regulate speed of locomotion in dinophilids as well. In the present work we examined the effect of external 5-HT and 5-HT biochemical precursor (5-hydroxytryptophan, 5-HTP) applications on 5-HT content within 5-HT-immunoreactive nerve elements and respective changes in gliding locomotion of juvenile and adult worms of two Dinophilid species. While morphology of the 5-HT-containing elements was similar in juveniles and adults of one species, 5-HT and 5-HTP application revealed different effects.

Materials and methods

Adult worms were cultured in the sea water with 33‰ salinity at 22°C and fed with nettles once a week after changing the water. Once a week adult worms were washed out from the

cultured dish and freshly hatched juveniles were collected upon appearance.

We used whole-mount immunocytochemistry with anti-5-HT- and acetylated α -tubulin antibodies to visualize 5-HT-containing nervous and ciliary structures, respectively. We used staining protocol described earlier (Kerbl et al., 2016). Briefly, worms were fixed in 4% paraformaldehyde in phosphate buffer saline (PBS, pH 7.4) overnight at 10°C. After washing in PBS worms were incubated in a mixture of primary antibodies: a-5-HT (Immunostar) 1:2000, α -tubulin (Sigma) 1:10000, for 72 h at 10°C. After washing the preparations were incubated in a mixture of Goat anti rabbit Alexa 488 and Goat anti mouse Alexa 633 secondary antibodies (Molecular Probes, both 1:1000) overnight at 10°C. After final washing the preparation were immersed in 70% glycerol and examined under LCSM Nikon A1 (Nikon, Japan). All specimens were examined as whole-mounts using appropriate wavelength-filters configuration settings, 0.5 μm thick optical sections were taken and processed with Nikon software to obtain the whole image. Optimal gain/offset settings were adjusted for non-incubated control animals, and then the same parameters were used to examine 5-HTP treated specimens.

To examine the speed of locomotion we used the video recording utilizing ocular DCM-150 camera (SkopeTek, China). Five worms

were used for each experimental trial. For track video recordings the worms were transferred into drop of seawater (150 µl) in a watch glass, and covered with a cover slip. After 1 min of recording the 5-HT or 5-HTP (15 µl 10⁻⁵ M) were added. After 10 min the other 1 min recording was performed. The tracks of individual animals were constructed and track length was analyzed using ImageJ software upgraded with Worm Tracker plugin. We used Graph Pad Prism for statistical analysis and graphs.

Results and discussion

Ciliary structures

D. gyrocladius and *D. taeniatus* juveniles demonstrate similar organization of ciliary structures. It includes circular ciliary bands on head and trunk region and ventral ciliary field on the ventral side of the body. Two ciliary bands located on head region, both join the ventral ciliary field on ventral side and are unclosed on dorsal side. Six ciliary bands are located in a trunk region (Fig. 1A, C). They also join the ventral ciliary field on ventral side. Both species demonstrate dense ciliation on the ventral side, represented by ventral ciliary field (Fig. 1A, C). Organization of the ciliary structures in adults of both species remains the same pattern as in juveniles though the number of trunk ciliary bands increases twice in *D. taeniatus*. It includes seven ciliary bands in trunk region in *D. gyrocladius* adults and eleven ciliary bands in *D. taeniatus* adults. Both species demonstrate dense ciliation on the ventral side, represented by ventral ciliary field (Fig. 1E, G). Thus, both species have similar pattern of ciliary locomotory structures in juveniles and in adults.

5-HT-immunopositive components of the nervous system

In both species the nervous system includes the head neuropile, ventral cords and commissures, and peripheral nerve elements. Ventral nerve cords are located underneath the ventral ciliary field in both species. In *D. gyrocladius* 5-HT-immunopositive (5-HT-ir) cells are concentrated in the anterior part of the body closely to the anterior group of commissures, as de-

scribed previously (Kerbl *et. al.*, 2016). In *D. taeniatus* 5-HT-ir cells located as regular symmetric groups near each commissure. 5-HT-ir fibers underneath the ventral ciliary field organized more loosely in *D. gyrocladius* juveniles compared with *D. taeniatus* (Fig. 1B, D). In adults of both species the head neuropil became more compact and all parts of the nervous system contain more 5-HT-immunopositive fibers. In *D. gyrocladius* ventral network underneath the ventral ciliary field remained diffuse organization as in juveniles. In *D. taeniatus* ventral network becomes more regular and prominent, 5-HT-ir cells are located as regular symmetric groups near regular commissures (Fig. 1H). Thus, the general pattern of 5-HT-ir network underneath the ventral ciliary field remains similar in juvenile and adults of one species.

Incubation in 5-HT and 5-HTP

After incubation in 5-HT the 5-HT-ir revealed the same general organization of the nervous elements of *D. taeniatus* juvenile. However, both cell bodies and processes become brighter and more prominent compared with a control, preparations demonstrate high background (Fig. 2A, B). Incubation in 5-HTP leads to appearance of additional cell bodies in all parts of the 5-HT-ir nervous system. Note that most of the additional cells demonstrate character of receptor neurons: flask-shaped form and long sensory dendrite bearing cilia (Fig. 2C). Preparations demonstrate high background; all structures become brighter and more prominent compared with both 5-HT-treated and control (Fig. 2A–C). Similar changes in 5-HT-immunoreactivity occurred in *D. gyrocladius* juveniles and adults (data not shown). These results indicate that exogenous application of 5-HT and 5-HTP resulted in unambiguous increase of endogenous 5-HT level in the nervous system of the treated worms.

Gliding locomotion after 5-HT and 5-HTP application

Both species use ventral ciliary field for gliding locomotion and circular ciliary bands for swimming. The lengths of tracks represent the relative speed of the individual worms, each

group demonstrates the high variety of this parameter (Fig. 3). Nevertheless, the mean speed of control *D. gyrociliatus* and *D. taenius* juveniles is similar. Application of 5-HT and 5-HTP resulted in slight but statistically significant increase in speed of gliding locomotion (Fig. 3A, B). Adult *D. gyrociliatus* demonstrate approximately two times shorter tracks than adult *D. taenius* probably due to the compar-

ative smaller size of the worms. Contrary to juveniles, adult worms of *D. gyrociliatus* demonstrate decrease the gliding locomotion after 5-HT application. 5-HTP have smaller effect but less pronounced (Fig. 3C). Neither 5-HT nor 5-HTP application produce any effect on *D. taenius* gliding locomotion (Fig. 3D).

Thus, pharmacological experiments demonstrated opposite reaction of juveniles and

adults dinophilid worms to 5-HT and 5-HTP application. While 5-HT increased speed of juveniles gliding locomotion, the same concentrations of 5-HT decreased significantly or did not affect the locomotion of adults.

To summarize, our results demonstrate that juvenile and adult Dinophilid worms possess well developed 5-HT-containing nervous system underlying locomotory ciliary structures. Similar organization of locomotory system is characteristic for many Lophotrochozoa larvae and adult flatworms (Stevenson et al., 2010). Serotonin neurons appear as first nervous elements in larval development (Schmidt-Rhaesa et al., 2016) and serotonin system is known to be

involved in regulation of locomotion in land and aquatic molluscs (Gosselin et al., 1962; Pavlova, 2001; Longley, 2008). In all species investigated so far 5-HT application or stimulation of 5-HT synthesis by application of biochemical precursor, 5-HTP, enhanced ciliary beating and resulted in respective increase of speed in ciliary driven locomotion in both larval and adult stage of life (Gosselin et al., 1962; Christopher et al., 1999; Goldberg et al., 1994, 2011). In our experiments, 5-HT and 5-HTP application also resulted in increase in 5-HT content within nervous structures and respective increase in speed of the gliding locomotion in juvenile worms. To the contrary, the same treatment had

no effect on adult species of *D. taeniatus* or even decreased the gliding speed in adult *D. gyrociliatus*. Paradoxically opposite effects of 5-HT on the locomotion of juveniles and adults may indicate that different receptors are involved in 5-HT pathways in young juvenile and mature individuals. The investigation of 5-HT signalling pathways in different stages of Dinophild development is necessary to confirm this hypothesis.
