ABSTRACT: The results of long-term (1973–2005) authors' studies of the inland water gastropod of Western Siberia are given. Following to the most recent taxonomic surveys (Starobogatov et al., 2004; Kantor, Sysoev, 2005), we count 134 gastropod species belonging to nine families to dwell in the region under discussion. Most of them (86 out of 134) are pulmonates. The most diverse fauna of water snails was found in the Irtyshian zoogeographical province, and the least diverse — in the Lower Obian one. There is a clear latitudinal gradient of gastropod species richness in Western Siberia. Differences in species composition between zoogeographical provinces as well as possible pathways of snails' migration through Western Siberia are discussed. It was found, the gastropod fauna of Western Siberia inland waters has a European origin with a participation of autochthonous species and migrants from Eastern Siberia and Northern America.

KEYWORDS: inland water gastropods, Western Siberia, malacofauna, zoogeography.

РЕЗЮМЕ: В статье изложены результаты многолетних (1973–2005 гг.) исследований авторов, посвященных пресноводным гастроподам Западной Сибири. Следуя современным таксономическим монографиям и обзорам (Старобогатов и др., 2004; Кантор, Сысоев, 2005), мы насчитываем в составе малакофауны Западной Сибири 134 вида пресноводных моллюсков, относящихся к девяти семействам. Большая часть видов (86 из 134) принадлежит подклассу Pulmonata. Наибольшее видовое разнообразие водных гастропод выявлено в Иртышской зоогеографической провинции, наименьшее — в Нижнеобской. В Западной Сибири установлен четко выраженный широтный градиент видового богатства водных брюхоногих моллюсков. Об-

суждаются различия в видовом составе отдельных зоогеографических провинций, а также возможные пути миграции моллюсков по территории Западной Сибири. Установлено, что фауна водных гастропод Западной Сибири имеет европейское происхождение, в ней есть также автохтонные виды и виды, мигрировавшие из Восточной Сибири и Северной Америки.

КЛЮЧЕВЫЕ СЛОВА: брюхоногие моллюски континентальных вод, Западная Сибирь, малакофауна, зоогеография.

Introduction

The history of studying of the Western Siberian continental malacofauna started more than 170 years ago, when F. Gebler (1829) published his brief list of mollusc species which were kept in the Barnaul Museum. In the XIX century, several prominent scientists (A.F. Middendorff, C.A. Westerlund, I.D. Czerski were among them) have explored molluscs of the Western Siberian waterbodies (Westerlund, 1877, 1884, 1897; Mozley, 1936). However, down to the middle of the XX century investigations in this area were rather sporadic, and the greater part of Western Siberia has remained not surveyed by malacologists. V.I. Zhadin used these incomplete and desultory data on the Western Siberian water gastropods in his well-known monograph on fresh- and brackish water Mollusca of the former USSR (Zhadin, 1952), where he listed 34 species of snails inhabiting the region under discussion (Table 1).

The first attempt to realize a complete and comprehensive survey of the Western Siberian water malacofauna was undertaken by the Tomsk hydrobiological school under leadership of Prof. B.G. Johansen in the 1950–1970s. B.G. Johansen and his disciples (E.A. Novikov, V.N. Dolgin, V.A. Gundrizer, E.S. Frolova) explored different parts of the region and published a great number of papers devoted to species composition, taxonomy, ecology and practical significance of freshwater molluscs (Novikov, 1971; Frolova, 1973; Dolgin, Johansen, 1976; Gundrizer, 1984 and others). As a result of this work, E.A. Novikov (1983) published a concise report where he estimated diversity of Western Siberia freshwater gastropods. In total, he count-

ed 89 species of snails in the waterbodies of the region (see Table 1).

Species interpretations and nomenclature used by B.G. Johansen's school corresponded to the state of malacological taxonomy of those days. Since the latter half of the 1960s, a numerous taxonomic issues by Ya.I. Starobogatov and his collaborators and disciples began to be published. To date, the traditional system of most families of palaearctic freshwater molluscs has undergone a drastic change (Starobogatov, 1994). In particular, the number of species and genera, which are thought by Ya.I. Starobogatov's school to be valid is several times more than the analogous numbers that their colleagues in Western Europe can recognize (see Meier-Brook, 1993; Starobogatov, 1994; Korniushin, 2002 for review). From the point of view of Ya.I. Starobogatov's school, many of those species, which are accepted by Zhadin (1952) as well as by modern Western European taxonomists (Glöer, 2002; Glöer, Meier-Brook, 2003), are, in reality, complexes of species, and should be split into several taxa of a species rank (Kruglov, Starobogatov, 1987; Starobogatov, 1994).

As a result of these changes, a need for repeated faunistic inquiry of inland water gastropods of Western Siberia has arisen. Moreover, some geographic subregions of this territory have not been ever included into a malacofaunistic survey.

Here we present, in a brief form, the main results of our long-term taxonomic and faunistic study devoted to fresh- and brackish water gastropods of Western Siberia. While studying, we took into consideration all the taxonomic novelties that were offered in 1970–2000s by Ya.I. Starobogatov and his school (see Starobogatov

Table 1. Diversity of gastropods in the inland waterbodies of Western Siberia

Family	Number of species according to different authors		
	V.I. Zhadin (1952)	E.A. Novikov (1983)	Own data
<i>subclassis Pectinibranchia (= Prosobranchia auct., partim)</i>			
Viviparidae	1	1	1
Valvatidae	2	13	25
Hydrobiidae	1	—	14
Bithyniidae	2	6	8
<i>subclassis Pulmonata</i>			
Acroloxidae	1*	1	1
Bulinidae	16**	3	4
Planorbidae		24	33
Lymnaeidae	9	36	40
Physidae	2	5	8
Total	34	89	134

*Zhadin (1952) includes the genus *Acroloxus* into the family Ancyliidae

**Zhadin (1952) includes the family Bulinidae into the family Planorbidae s.lato

et al., 2004; Kantor, Sysoev, 2005 for review). Thus, our species list is the third attempt, after V.I. Zhadin (1952) and E.A. Novikov (1983), to estimate an overall species diversity of snails of the continental waters of Western Siberia. It should be noted, however, that there are many taxonomic and nomenclature problems with Siberian water molluscs to be resolved in further studies. Therefore our results should be regarded only as interim ones and these are opened for eventual subsequent alterations and additions.

Material and methods

The base of the investigation was authors' own field studies that were carried out during years 1973–2005 in different parts of Western Siberia (Tomsk, Novosibirsk, Omsk, Altay and Tyumen Regions, Northern and Central Kazakhstan). All malacological materials collected by the authors are stored in the Museum of Siberian Aquatic Molluscs (established in 2003 as a scientific sub-unit of the Omsk State Pedagogical University). In whole, these collections include more than 60000 specimens of molluscs, both gastropods and bivalves. Besides, we had an opportunity to examine a large collection of molluscs gathered by Dr. V.N. Dolgin (Tomsk) in the waterbodies of the north-

ern part of Western Siberia. A small part of this collection is stored in the Museum of Siberian Aquatic Molluscs as well as collections of Dr. D.A. Razmashkin, A.V. Ubasskin, A.V. Panin, P.V. Chashchin and other researchers. In addition, we examined the largest malacological collections of Russia. The collections of the Zoolo-gical Institute of RAS (Saint-Petersburg), of the Zoological Museum of the Institute of Plant and Animal Ecology of RAS (Yekaterinburg) and of the Biology and Biophysics Research Institute of the Tomsk State University are among them. These collections are originated from all parts of Western Siberia and include samples that have been made from the 1840s to date.

It is worth to note, we apply the term 'Western Siberia' in a somewhat unusual sense, otherwise than geographers commonly do (see, for example, Richter, 1963). In addition to the water-bodies situated in the Western Siberian plain, those of the eastern mountside of the Urals have been included into the scope of our study, whereas we have not explored the territory of Altay Mountains. The Altaian malacofauna is distinct from that of adjacent lowland regions by its origination and by a high degree of endemism. It is more similar to the malacofauna of Western Mongolia and Upper Yenisei drainage basin than to the malacofauna of the Western Siberia

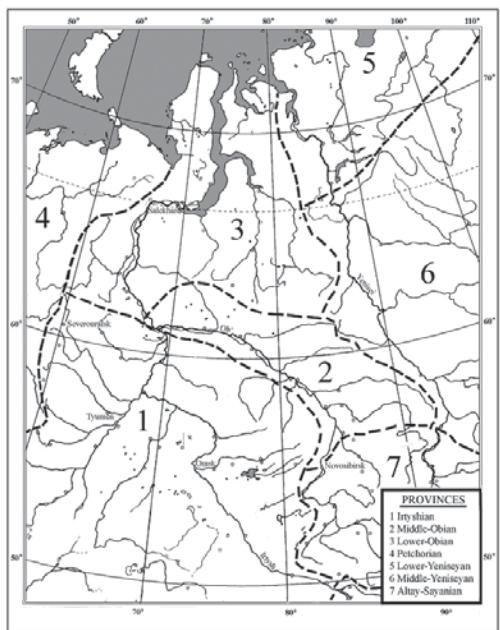

Fig. 1. Zoogeographical zonation of the Western Siberia territory (according to Starobogatov, 1986, with additions after Dolgin, 2001).

Рис. 1. Зоогеографическое районирование территории Западной Сибири (по Старобогатову, 1986, с дополнениями по Долгину, 2001).

plain. According to Ya.I. Starobogatov's zoogeographic zonation (Starobogatov, 1986), the territory that we designate here as 'Western Siberia' belongs to three provinces: Irtyshian (IRT), Middle Obian (MOB) and Lower Obian (LOB) (Fig. 1).

The species identification was carried out using both conchological and anatomical features. We followed the recent key (Starobogatov et al., 2004) in delimitation of species, and Catalogue of Russian molluscs (Kantor, Syssov, 2005) in their naming. Always, when it was possible, we used the type series of species from the collection of the Zoological Institute of RAS as well as original descriptions of taxa. During our work, we obtained frequent advice of the late Dr. Ya.I Starobogatov who has confirmed some of our faunistic findings.

We used the Ochiai's index of association (Ochiai, 1957; Pesenko, 1982) as a measure of faunistic similarity between zoogeographical

provinces. This index is similar to well-known indices of Jaccard and Czekanowski-Sörensen, but it utilizes the geometric mean instead of the arithmetic one, and this is considered as an advantage of the Ochiai's index (Malyshev, 2001). For the comparative analyses we used lists of species inhabiting two other faunistic provinces adjacent to Western Siberia: Pechorian (Leshko, 1998; Leshko et al., 2001) and Lower Yenisean (Gundrizer, 1984; Dolgin, 2001).

Results and discussion

In total, 134 species of Gastropoda are recorded to date in the inland waterbodies of Western Siberia (Table 1, 2). These species belong to nine families, one of which (Hydrobiidae) occurs in brackish lakes of Northern and Central Kazakhstan only. The rest are freshwater dwellers. Our species list is well longer than both by V.I. Zhadin (1952) and E.A. Novikov (1983), and this is due to the recent changes in molluscan taxonomy (see Materials and methods) rather than because of describing of new species.

Species richness of water pulmonates in Western Siberia exceeds significantly that of pectinibranch (=prosobranch) gastropods (86 vs. 48 species, respectively), and such a disproportion is common for the malacofaunas of temperate zone of Northern Hemisphere (Starobogatov, 1970).

The most diverse fauna of water snails was found in the Irtysh River basin (i.e. Irtyshian province), that covers the south-western part of the region, and the least diverse fauna was found in Lower Obian province, that is the northernmost one, and stretches to the shore of the Kara Sea (see Table 2). The overall species richness of water snails decreases along a latitudinal transect and reaches its minimum north of the Arctic Circle. This fact corresponds well to modern ideas on the spatial diversity gradients (Starobogatov, 1970; Chernov, 1991; Gaston, 2000), in particular, to the energy-based hypothesis (Hawkins et al., 2003), which explains the decreasing of species richness from the

Equator to poles by appeal to the equator-pole asymmetry of solar energy allocation.

The highest levels of faunistic similarity were found between pairs of adjacent provinces: IRT and SOB, and SOB and NOB (Table 3).

It does not conform with an opinion of Ya.I. Starobogatov (1986), who offered to include Irtyshian province on the one hand, and two Obian provinces on the other hand, into different faunistic superprovinces, namely into Euro-

pean-Central-Asian and Siberian, respectively. Our data show that the gastropod fauna of Irtyshian province is more similar to the faunas of the two Obian provinces than to the fauna of the Pechora River basin which belongs to European-Central Asian superprovince (see Table 3). However, such a contradiction has, probably, arisen due to the taxonomic bias only. Our analyses did not include bivalve species, whereas Ya.I. Starobogatov (1970, 1986) used both bivalve and gastropod taxa in his zoogeographical zonation. Therefore, zoogeographical studies on the Western Siberian malacofauna should be continued.

Moreover, two 'Northern' provinces under study (i.e. Lower Obian and Lower Yenisean) are more similar, in respect of its snail fauna, to each other than to the two 'Southern' (i.e. Irtyshian and Middle Obian) ones, and constitute a separate cluster in the dendrogram (Fig. 2). The gastropod fauna of Pechorian province differs clearly from the faunas of all Siberian provinces (see Fig. 2), and this may be regarded as an evidence of a some peculiarity of the Western Siberia freshwater malacofauna that is enriched with species of Eastern Siberian and even of Northern American origin as well as with endemic taxa (Starobogatov, 1970; Kruglov, Starobogatov, 1981). Eleven species (or 8.2%) are endemics of Western Siberia. These are *Cincinnatia antiquilina*, *Caspiohydrobia borealis*, *C. johanseni*, *Aenigmomphiscola kazakhstanica*, *Lymnaea napasica*, *L. dolgini*, *L. obensis*, *L. novikovi*, *L. juribeica*, *L. ulaganica*, *Anisus johanseni*, which, possibly, have arisen in the Western Siberian center of speciation that, prob-

ably, existed in the late Neogene (Kruglov, Starobogatov, 1981).

Gastropod species of the Western Siberia water malacofauna belong to 13 zoogeographical groups, the largest of which is the European-South-West-Siberian one that includes 42 species, or 31.3% (Table 4). Thus, a large portion of gastropod species having a European origin does not occur in Siberia beyond its southwestern part. Perhaps, it may be explained by severe climatic conditions of Siberia.

Nevertheless, the freshwater snail fauna of Western Siberia has, as a whole, a 'European' character, especially as compared with the malacofauna of the Eastern Siberian waterbodies. Indeed, only 44 (or 33%) out of the species inhabiting Western Siberia do not occur in Europe, that confirms assumption of Ya.I. Starobogatov (1970, 1986) that those species, which migrated to Siberia from Europe during the Neogene and Pleistocene, constitute a basis of the recent freshwater malacofauna of Western Siberia. These cold-resistant species, having a boreal European origin, have replaced endemic heat-loving forms of gastropods and bivalves, which were very abundant and diverse in the neogene waterbodies of Western Siberia (Lindholm, 1932a, b; Starobogatov, 1970; Zykin, 1979). Probably, the main path of migration was situated in Northern Kazakhstan and Southern Urals. The greatest portion of European species in local faunas is observed now just here. Toward the northeast, a portion of species having either Siberian or Northern American origin increases, and a portion of European species as well as overall species richness decrease in the

same direction (Andreev et al., 2004). The most peculiar is the gastropod fauna of the Yamal Peninsula that is similar in its origin and species composition to the fauna of Lower Yenisean province (Dolgin, 2001). It is the poorest local fauna in respect of species and it consists mainly of Siberian endemic forms. According to V.N. Dolgin's (2001) data, supplemented by our examination of museum collections, only 15 species of freshwater Gastropoda inhabit the Yamal waterbodies, whereas more than 60 species of snails were recorded from the waterbodies of the Ilmeny Reserve (Southern Urals, south-western part of the Irtysh River basin). The causes of it are, perhaps, twofold. First, severe climate of the Yamal Peninsula, situated north of the Arctic Circle, and, second, the absence of a large transit river, which would be a road for snails' downstream dispersal. For the greater part of Western Siberia such a function is performing by the Irtysh and Ob' Rivers which flow in north direction, however, the Yamal Peninsula is situated northwestwardly of the Ob' bay, and it limits greatly an ability of freshwater gastropods to reach this territory by a downstream drift.

Thus, from the faunogenetic prospect, the gastropod fauna of inland waterbodies of Western Siberia constitutes a derivative from the boreal European species complex supplemented by few autochthonous species and by migrants from Eastern Siberia and Northern America. The 'European' character of the fauna is expressed most clearly in the southwestern part of Western Siberia where boreal European species predominate.

Acknowledgements

The authors wish to thank all colleagues who kindly provided their collections of snails for examination: Dr. V.N. Dolgin (Tomsk), Dr. D.A. Razmashkin (Tyumen), A.V. Ubasskin (Pavlodar), P.V. Chashchin (Miass), M.E. Grebennikov (Yekaterinburg), L.N. Stepanov (Yekaterinburg). Besides, we are thankful to Dr. I.M. Khokhutkin, Dr. P.V. Kiyashko, L.L. Yarochnovich and N.G. Erokhin who helped us during our work in museums.
